A Recap of What we Learned Last Class

- Describe the goals & functions of data mining
- Understand the statistical limits on data mining
- Describe the data mining process
- What is "frequent itemsets" & the application of this concept
- Explain how and why "association rules" are constructed
- Use to populate both concepts

Learning Objectives for Today's Class

- Describe the different steps of the k-means algorithm
- Cluster using k-means (by hand)
- Cluster using k-means (software)
 - · **R**
 - Tableau

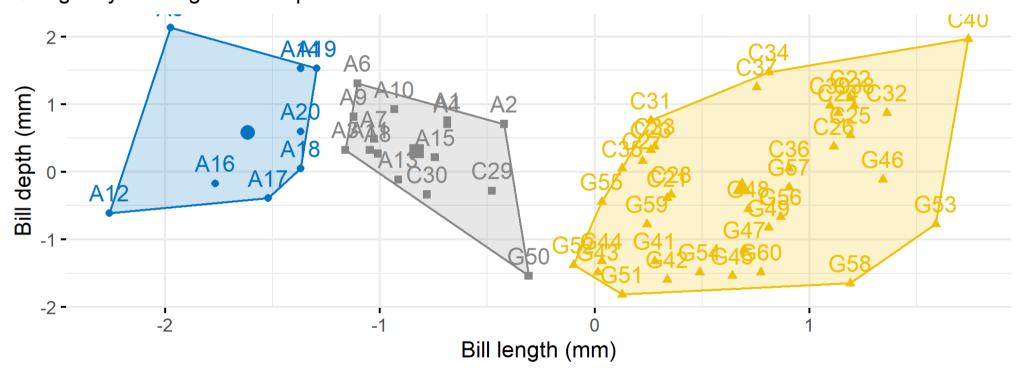

An Overview of Clustering Techniques

The Problem of Clustering

- Given a **set of (high-dimensional) observations**, with a notion of **distance** between observations, **group the observations** into **some number of clusters**, so that:
 - Members of a cluster are close/similar to each other
 - Members of different clusters are dissimilar.
- Usually:
 - The observations are in a high-dimensional space
 - Similarity is defined using a distance measure, e.g.,
 - Euclidean, Cosine, Jaccard, edit distance, etc.

Clustering in 2D Space: Clustering Results

Clustering of a sample of 60 penguins into three groups Using only bill length and depth

Comments on the 2D Clustering Problem

Even though the 2D Space clustering problem is the easiest problem to "solve" since we can benefit by plotting the data, **clustering is hard**.

Some important questions:

- With all the variables being numerical, we often assume **Euclidean distance**. This can be problematic when:
 - variables have significantly different scales
 - we are including information that is not pertinent to grouping
- How do you determine the number of clusters (\$k\$)?
- How to represent a cluster of many points?
- How do we determine the "nearness" of clusters?

An Overview of Clustering Methods

Categories	Abb. name	Volume			Variety		Velocity	Other criterion
		Size of Dataset	Handling High Dimensionality	Handling Noisy Data	Type of Dataset	Clusters Shape	complexity of Algorithm	Input Parameter

k-means Algorithm

General Idea

The K-Means algorithm clusters data by trying to separate samples in n groups of equal variance, minimizing a criterion known as the **inertia** or **within-cluster sum-of-squares** (see below). This algorithm requires the **number of clusters to be specified**.

$$\sum_{i=0}^n \min_{\mu_j \in C} (\left|\left|x_i - \mu_j
ight|\right|^2)$$

Inertia is a measure of how internally coherent clusters are; however, it suffers from various drawbacks:

- Inertia makes the assumption that clusters are convex and isotropic, which is not always the case. It responds poorly to elongated clusters, or manifolds with irregular shapes.
- Inertia is not a normalized metric: we just know that lower values are better and zero is optimal. But in very high-dimensional spaces, Euclidean distances tend to become inflated.

The Steps of the K-Means Algorithm

In basic terms, the algorithm has three steps.

- Step 0 chooses the initial centroids, with the most basic method being to choose k samples from the dataset X. After initialization, K-means consists of looping between the remaining two steps.
- Step 1 assigns each sample to its nearest centroid.
- The second step creates new centroids by taking the mean value of all of the samples assigned to each previous centroid. The difference between the old and the new centroids are computed.

The algorithm repeats these last two steps the centroids do not move significantly.

Class Activity

Use the k-means algorithm to cluster the following observations. Use k=2 and Euclidean distance. We will use the class handout to walk you through the process.

Observation	X1	X2
1	1.0	1.0
2	1.5	2.0
3	3.0	4.0
4	5.0	7.0
5	3.5	5.0
6	4.5	5.0
7	3.5	4.5

Summary of Practical Issues

- Rescale numeric data prior to k-means implementation. The scaling can be:
 - a z-transformation similar to what we did in the example
 - a 0-1 scaling
 - converting count data into percentage or counts per a certain number of the population
 - etc.
- Use more than one metric to determine k when using k-means clustering
- Your cluster solution is not the end result, you will need to:
 - visualize it in appropriate way (simple representation as in the previous slide, spatially, time-based, etc.)
 - Attempt to explain the cluster membership using an appropriate binomial/multinomial model (e.g., see this analysis)

k-means in Tableau

Let us use Tableau to implement the k-means clustering implementation on the 60 sample observations from the penguins dataset as shown in Slide 6 of this presentation.
